ABSTRACT

Aims. Optically thin plasmas may deviate from thermal equilibrium and thus, electrons (and ions) are no longer described by the Maxwellian distribution. Instead they can be described by κ -distributions. The free-free spectrum and radiative losses depend on the temperature-averaged (over the electrons distribution) and total Gaunt factors, respectively. Thus, there is a need to calculate and make available these factors to be used by any software that deals with plasma emission.

Methods. We recalculated the free-free Gaunt factor for a wide range of energies and frequencies using hypergeometric functions of complex arguments and the Clenshaw recurrence formula technique combined with approximations whenever the difference between the initial and final electron energies is smaller than 10^{-10} in units of $z^2 \text{Ry}$. We used double and quadruple precisions. The temperature-averaged and total Gaunt factors calculations make use of the Gauss-Laguerre integration with 128 nodes.

Results. The temperature-averaged and total Gaunt factors depend on the κ parameter, which shows increasing deviations (with respect to the results obtained with the use of the Maxwellian distribution) with decreasing κ . Tables of these Gaunt factors are provided.

Key words. atomic processes – radiation mechanisms: general – ISM: general – galaxies: ISM

1. Introduction

Astrophysical plasma emission codes are a powerful tool for calculating spectra and energy losses in a plasma such as the interstellar or intergalactic medium and for comparing the results with observations. However, such plasmas are complex systems in which frequently made assumptions, like establishing the Maxwell-Boltzmann distribution (hereafter referred as Maxwellian distribution) of the electrons and ions, are not always fulfilled and may lead to erroneous interpretations of the plasma properties. We have therefore reexamined the nonrelativistic free-free Gaunt factor, which is the quantum correction for the semiclassical cross section of Kramers (1923). The factor has been the subject of many papers over the years, comprising analytical approximations (e.g., Menzel & Pekeris 1935; Elwert 1954; Grant 1958; Brussaard & van de Hulst 1962; Hummer 1988; Beckert et al. 2000) to the exact quantum mechanical expressions (in terms of hypergeometric functions) derived, for example, by Menzel & Pekeris (1935), Sommerfeld (1953, using nonrelativistic dipole approximation), Kulsrud (1954), and Biedenharn (1956), and detailed numerical computations first discussed in the seminal work of Karzas & Latter (1961, hereafter KL61) and followed by a series of publications during the past five decades.

Karzas & Latter computed the Gaunt factor using hypergeometric functions of complex variables and presented their results in graphical form. The problem reduces to calculating the solution of differential equations by means of power series of the real variable x (which is negative) at two regimes ($|x| > 1$ and $|x| \leq 1$)

with a very slow convergence when $|x| \rightarrow 1$. Since KL61, several authors recalculated the Gaunt factor with increasing precision and size of parameter space (e.g., O'Brien 1971; Carson 1988; Hummer 1988; Nicholson 1989; Janicki 1990; Sutherland 1998; van Hoof et al. 2014). Special care was taken to overcome the slow convergence of the solution by (i) redefining the regimes through a change in variables (O'Brien 1971), which has been adopted, in combination with KL61 formulae, in most of the calculations that followed; (ii) increase in precision; and (iii) by using the approximation of Menzel & Pekeris (1935, see discussion in van Hoof et al. 2014, who corrected a term in their formulae).

The Gaunt factor can be averaged over a distribution of electrons (also known as the temperature-averaged Gaunt factor) and then integrated over the full range in frequency (the total Gaunt factor). These in turn are used in the determination of the emission spectra and radiative losses by a plasma as a result of this process. In general, the averaging is made over a Maxwellian distribution of electrons, thus relying on the assumption that thermal equilibrium is the rule (see, e.g., Karzas & Latter 1961; Gayet 1970; Armstrong 1971; Feng et al. 1983; Carson 1988; Hummer 1988; Nicholson 1989; Janicki 1990; Sutherland 1998; van Hoof et al. 2014).

However, this condition may not be attained if high-energy electrons are injected into the system on timescales shorter than that needed to achieve thermalization (Livadiotis & McComas 2009) or when long-range forces are present in the plasma (Collier 2004). Deviations may also occur in the presence of strong temperature and/or density gradients (Collier 1993; Collier et al. 2004, see discussion in, e.g., Dudík et al. 2011 and references therein). An example of nonthermal distributions is

[★] Appendices are available in electronic form at
<http://www.aanda.org>

the so-called κ -distribution, which was first used by [Vasyliunas \(1968\)](#) to match the observed electron distribution in the Earth's magnetosphere. κ -distributions have also been used to explain the discrepancies observed in the abundances and temperatures in HII regions and planetary nebulae when derived using collisional excitation lines and optical recombination lines (see [Binette et al. 2012](#); [Nicholls et al. 2012, 2013](#)). The κ -distribution is characterized by a high-energy power-law tail and has the form

$$f_\kappa(E)dE = \frac{2E^{1/2}}{\pi^{1/2}(k_B T)^{3/2}} A_\kappa \left[1 + \frac{E}{(\kappa - 3/2)k_B T} \right]^{-\kappa-1} dE, \quad (1)$$

with

$$A_\kappa = \frac{\Gamma(\kappa + 1)}{\Gamma(\kappa - 1/2)(\kappa - 3/2)^{3/2}}, \quad (2)$$

and $\Gamma(x)$ denoting the gamma function of the variable x . When $\kappa \rightarrow \infty$, the Maxwellian distribution is recovered. As κ decreases, deviations from the Maxwellian distribution increase, reaching maximum when κ approaches 3/2 (Fig. 1, which displays the κ and Maxwellian distributions at different temperatures for electrons with energies varying between 10^{-2} and 10^4 eV). Similarly to the Maxwellian distribution, the mean energy of the κ -distribution is independent of κ and is given by $\langle E \rangle = 3/2k_B T$. Hence, T can be defined as the thermodynamic temperature for these distributions. For a review of the κ -distribution and its applications see [Pierrard & Lazar \(2010\)](#) and [Livadiotis & McComas \(2009\)](#).

[Dudík et al. \(2011, 2012\)](#) calculated the free-free contribution to the emission spectra and to the radiative losses of a plasma with the nonthermal distributions (κ and n distributions) and evolving under collisional ionization equilibrium conditions (CIE), that is, the number of recombinations equals the number of ionizations by electron impact. The authors calculated the temperature-averaged Gaunt factors for nonthermal distributions using the free-free Gaunt factors of [Sutherland \(1998\)](#).

The temperature-averaged and total Gaunt factors are needed for detailed simulations involving the coupling of the dynamical and thermal evolutions of the interstellar medium, bubbles and superbubbles (including the Local Bubble), and formation of galaxies, to name just a few. Hence, we carried out detailed calculations of the free-free Gaunt factor and of the temperature-averaged and total Gaunt factors for Maxwellian and κ -distributions (considering a large grid of κ parameters). We present these results in tabulated form to be used in any plasma emission software through convenient one- and two-dimensional interpolations.

The structure of this paper is as follows: Sect. 2 describes the calculation of the free-free Gaunt factor. Section 3 deals with the temperature-averaged and total Gaunt factor for Maxwellian and κ distributions of electrons. Section 4 describes the tabulated data, and we conclude in Sect. 5 with some final remarks.

2. Calculations of the Gaunt factor

The calculation of the free-free Gaunt factor in double and quadruple precision follows the prescription of [Janicki \(1990\)](#) with some adaptations taken from [Carson \(1988\)](#) and [van Hoof et al. \(2014\)](#). It is assumed that an electron with initial energy E_i absorbs a photon of energy $h\nu$. Thus, the electron transits to a higher state with an energy $E_f = E_i + h\nu$. The free-free Gaunt factor is then given by (KL61)

$$g_{\text{ff}} = \frac{2\sqrt{3}}{\pi} I_0 \left[I_0 \left(\frac{\eta_i}{\eta_f} + \frac{\eta_f}{\eta_i} + 2\eta_i\eta_f \right) - 2I_1 \sqrt{1+\eta_i^2} \sqrt{1+\eta_f^2} \right], \quad (3)$$

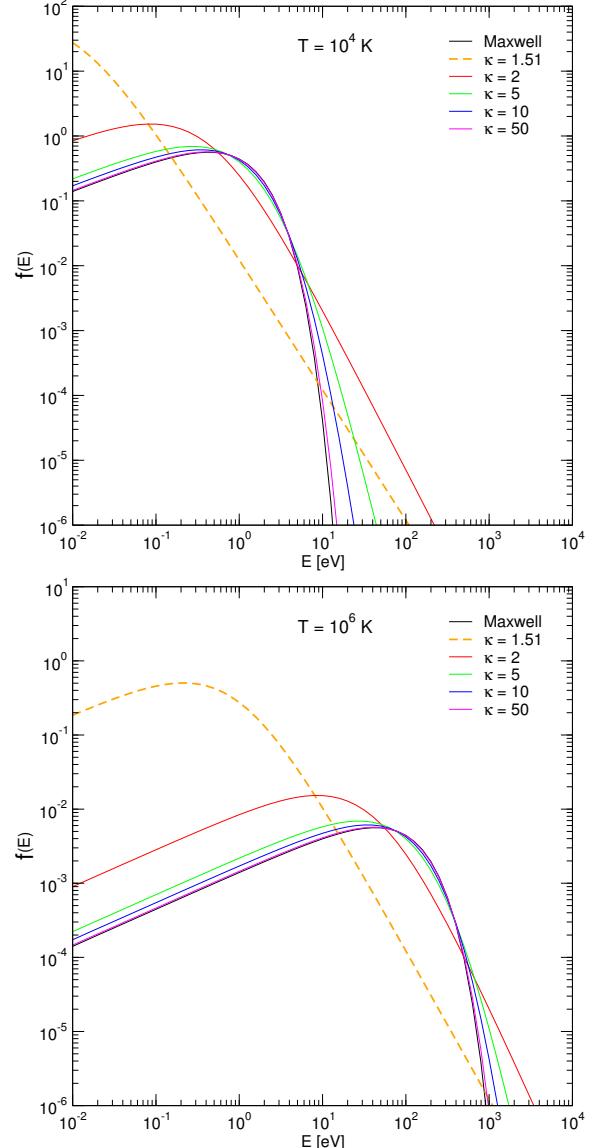

Fig. 1. Not normalized Maxwellian and κ -distributions (with different κ) at 10^4 K (top) and 10^6 K (bottom panel). The largest deviation of the Maxwellian distribution occurs for the lowest κ , showing an increase in electrons at the low- and high-energy ranges when compared to the Maxwellian distribution.

where $\eta_{i,f}^2 = 1/\epsilon_{i,f}$, $\epsilon_i = E_i/Z^2 Ry$ and $\epsilon_f = E_f/Z^2 Ry$ are the electron scaled initial and final energies, respectively; Ry is the infinite-mass Rydberg unit of energy, and Z the atomic number of the ion. The functional I_l (with $l = 0.1$) is defined as

$$I_l = \frac{1}{4} \left(\frac{4\eta_i\eta_f}{(\eta_i - \eta_f)^2} \right)^{l+1} e^{\pi|\eta_i - \eta_f|/2} \frac{|\Gamma(l+1+i\eta_i)\Gamma(l+1+i\eta_f)|}{\Gamma(2l+2)} G_l, \quad (4)$$

where G_l is a real function given by

$$G_l = (1-x)^{-i\eta_i-i\eta_f} {}_2F_1(a, b; c; x) \quad (5)$$

with $x = -4\eta_i\eta_f/(\eta_i - \eta_f)^2$ (which is always negative), $a = l + 1 - i\eta_f$, $b = l + 1 - i\eta_i$, and $c = 2l + 2$; ${}_2F_1(a, b; c; x)$ is the hypergeometric function, which satisfies the equation

$$x(1-x)F'' + [c - (a + b + 1)x]F' - abF = 0. \quad (6)$$

G_l satisfies the equation (Janicki 1990)

$$x(1-x^2)G'' + (1-x)f_1 G' + f_2 G = 0, \quad (7)$$

with $f_1 = c + x(2d-a-b-1)$ and $f_2 = x[d^2+ab-d(a+b)]-ab+dc$. Thus, the free-free Gaunt factor determination reduces to the calculation of solutions for G_l , and therefore for I_l , for $l=0, 1$ in terms of a power series in x for $|x| < 1$ and in $y = -1/x$ for $|x| > 1$ (KL61). These solutions converge very slowly near 1, but a change in variables to (Janicki 1990)

$$y = \begin{cases} x/(x-1) & \text{if } |x| \leq 1.61804 \\ -1/x & \text{if } |x| > 1.61804 \end{cases} \quad (8)$$

facilitates the calculation. The threshold results from equating $|x|/(|x|-1)$ to $-1/|x|$ and taking into account that $x < 0$ (see text above). Another step comprises the usage of the Clenshaw recurrence formula to calculate G_l at each regime by means of a series of terms. The number of terms n to be considered in the sum to within a certain precision, for example, $10^{-\delta}$, is given by $-\delta/\log|x/(x-1)|$ (for $|x| \leq 1.61804$) and $-\delta/\log|-1/x|$ ($|x| > 1.61804$). For further details see Janicki (1990).

In the range $\epsilon_{i,f}^{3/2}/w \leq 10^{-4}$, with $w = \epsilon_f - \epsilon_i = h\nu/Z^2Ry$, the exact solution fails (see Carson 1988; Hummer 1988; van Hoof et al. 2014). Hence, the approximation of Menzel & Pekeris (1935) with the correction by van Hoof et al. (2014) is used:

$$g_{ff} = 1 + c_1 \frac{1+k^2}{\chi^2} + c_2 \frac{1-4/3k^2+k^4}{\chi^4} + c_3 \frac{1-1/3k^2-1/3k^4+k^6}{\chi^6}, \quad (9)$$

with $k = \eta_f/\eta_i$, $\chi = [(1-k^2)\eta_f]^{1/3}$, $c_1 = 0.1728260369\dots$, $c_2 = -0.04959570168\dots$, and $c_3 = -0.01714285714\dots$. The maximum error in this approximation is smaller than 5.5×10^{-10} (van Hoof et al. 2014).

Figure 2 displays the variation of the free-free Gaunt factor with the normalized initial electron energy (top panel) for specific photon energies running from $\log(h\nu/Z^2Ry) = 8$ through -4 with steps of $\text{dex} = 1$, and with the normalized photon energy (bottom panel) for initial electron energies of $\log(E_i/Z^2Ry) = -5$ through 8 with steps of $\text{dex} = 1$. These Gaunt factors overlap with those reported by van Hoof et al. (2014) and Sutherland (1998).

3. Temperature-averaged and total Gaunt factor

The energy spectrum by free-free emission from electrons with an energy distribution $f(E)$ is given by (see, e.g., Kwok 2007)

$$\frac{dP_{ff}}{d\nu} = \frac{8\pi^2}{c^3} \left(\frac{2}{3m_e}\right)^{3/2} e^6 z^2 n_e n_{Z,z} \int_{h\nu}^{+\infty} \frac{1}{E^{1/2}} f(E) g_{ff}(E, \nu) dE, \quad (10)$$

where ν is the frequency of the emitted photon, T is the temperature, k_B is the Boltzmann constant, n_e is the electron density, $n_{Z,z}$ is the number density of ion with atomic number Z and ionization stage z . For electrons with a κ or Maxwellian ($\kappa \rightarrow \infty$) distribution, and after a suitable change of variables, Eq. (10)

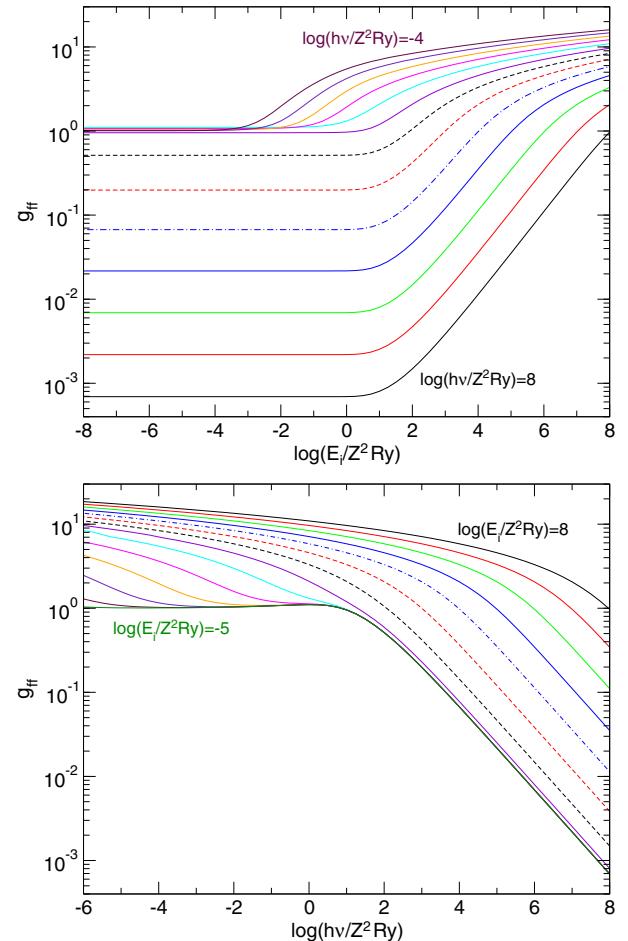

Fig. 2. Free-free Gaunt factor variation with the normalized initial electron energy (top panel) for specific photon energies running from $\log(h\nu/Z^2Ry) = 8$ through -4 with steps of $\text{dex} = 1$, and with the normalized photon energy (bottom panel) for initial electron energies of $\log(E_i/Z^2Ry) = -5$ through 8 with steps of $\text{dex} = 1$.

becomes

$$\frac{dP_{ff}}{du} = C_{ff} z^2 n_e n_{Z,z} T^{1/2} \times \times \begin{cases} \int_0^{+\infty} g_{ff}(\gamma^2, u) \frac{A_\kappa}{[1 + \frac{x+u}{\kappa-3/2}]^{\kappa+1}} dx & \text{if } \kappa > 3/2 \\ e^{-u} \int_0^{+\infty} g_{ff}(\gamma^2, u) e^{-x} dx & \text{if } \kappa \rightarrow \infty, \end{cases} \quad (11)$$

where $C_{ff} = 16 \left(\frac{2\pi}{3m_e}\right)^{3/2} \frac{e^6 k_B^{1/2}}{hc^3} = 1.4256 \times 10^{-27}$, and the parameters x, u and γ have the forms

$$x = \frac{E}{k_B T} - \frac{h\nu}{k_B T}, \quad u = \frac{h\nu}{k_B T} \quad \text{and} \quad \gamma^2 = \frac{z^2 Ry}{k_B T} = z^2 \frac{1.579 \times 10^5}{T}. \quad (12)$$

The integral on the right-hand side of Eq. (11) is the temperature-averaged Gaunt factor (KL61). Integration of Eq. (11) over the photon frequency spectrum gives the total free-free power associated with an ion (Z, z)

$$P_{ff}(T) = C_{ff} z^2 n_e n_{Z,z} T^{1/2} \int_0^{+\infty} \langle g_{ff}(\gamma^2, u) \rangle f(u) du, \quad (13)$$

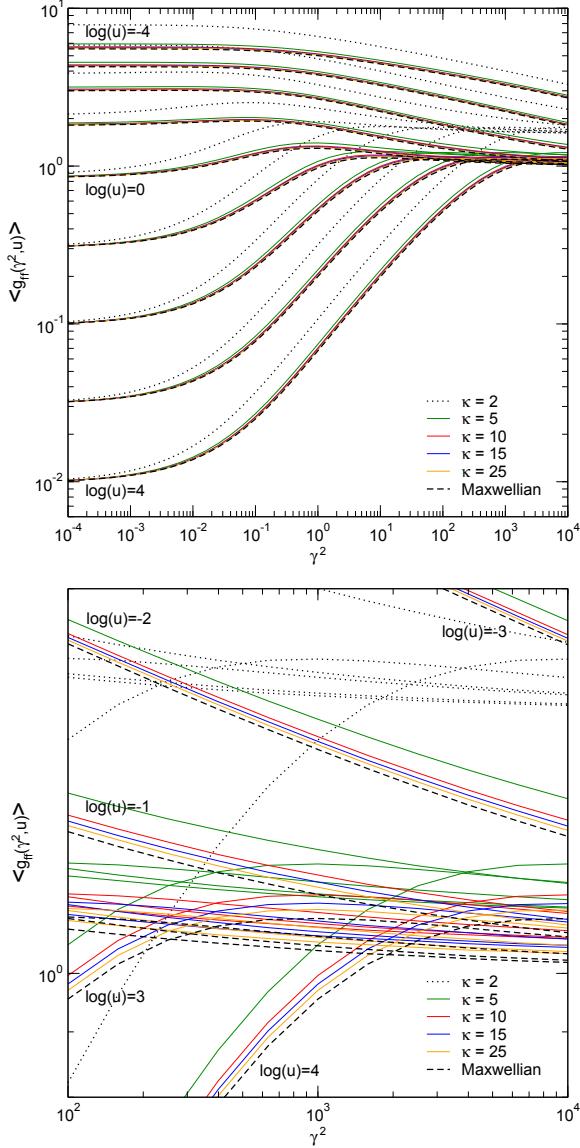

Fig. 3. Temperature-averaged Gaunt factors calculated for $\kappa = 2, 5, 10, 15$, and 25 and Maxwellian distributions of electrons for the range $10^{-4} \leq \gamma^2 \leq 10^4$ (top panel) and zoomed-in to the region $\gamma^2 \in [10^2, 10^4]$ and $\langle g_{ff}(\gamma^2, u) \rangle \in [0.8, 2]$ (bottom panel).

with $f(u) = e^{-u}$ (for $\kappa \rightarrow \infty$; Maxwellian distribution) and $f(u) = 1$ for $\kappa > 3/2$ (κ distribution). The total free-free Gaunt factor is defined as (see, e.g., KL61)

$$g_{ff}(T) = \int_0^{+\infty} \langle g_{ff}(\gamma^2, u) \rangle e^{-u} du, \quad (14)$$

and, thus, can be calculated for both distributions.

Figures 3 and 4 display the variation with γ^2 of the temperature-averaged, $\langle g_{ff}(\gamma^2, u) \rangle$, and total free-free, $g_{ff}(T)$ Gaunt factor. The results correspond to $\kappa = 2, 5, 10, 15, 25$ and ∞ (the latter value corresponds to the Maxwellian distribution).

The temperature-averaged Gaunt factors depend on the κ parameter - with the decrease of κ , the deviations of $\langle g_{ff}(\gamma^2, u) \rangle$ increase with respect to the Maxwellian-averaged value (Fig. 3). The strongest deviation always occurs for $\kappa \rightarrow 3/2$. These deviations depend strongly on the γ^2 (i.e., on the temperature) and mildly on the u (i.e., on the frequency) parameters. As γ^2 tends to $-\infty$, the $\langle g_{ff}(\gamma^2, u) \rangle$ for different κ approximates the

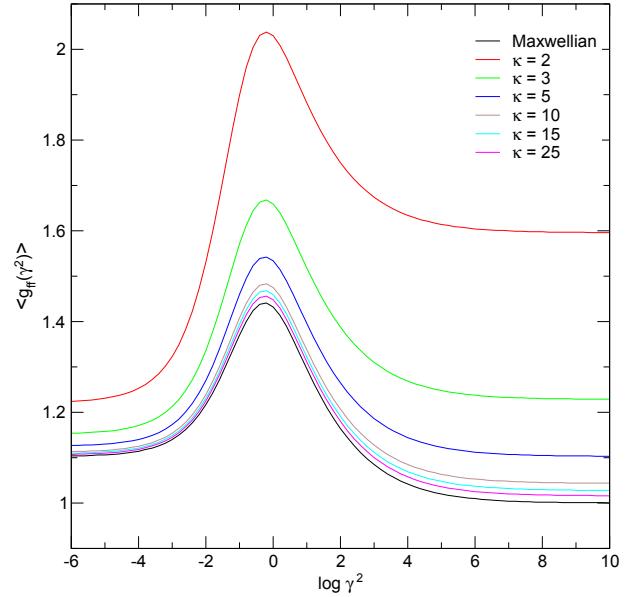

Fig. 4. Total free-free Gaunt factor calculated for $\kappa = 2, 3, 5, 10, 15$, and 25 and Maxwellian distributions. The maximum of $g_{ff}(T)$ moves to the left with the increase in κ .

Maxwellian-averaged value (black dashed line; top panel of Fig. 3), which also depends on the value of u . With the decrease of u (for $u < 1$) the degree of blending among the temperature-averaged Gaunt factors diminishes. With an increase in γ^2 (decrease in temperature), the deviations become larger and more pronounced for $\gamma^2 > 10$ (bottom panel of Fig. 3). However, regardless of the value of γ^2 , the $\langle g_{ff}(\gamma^2, u) \rangle$ shows a small variation for all $\kappa \geq 5$ even for $\gamma^2 > 10$.

The total Gaunt factor shows a similar dependence on κ for the different γ^2 as $\langle g_{ff}(\gamma^2, u) \rangle$. That is, the deviations increase with increasing γ^2 (Fig. 4). The total Gaunt factor maximum decreases with increasing κ from 2.038 to 1.441 for $\kappa = 2$ and $\kappa \rightarrow \infty$, respectively. When $\gamma^2 \rightarrow \infty$, the total Gaunt factor tends to 1.596 for $\kappa = 2$, decreasing toward 1.0 with $\kappa \rightarrow \infty$ (the Maxwellian distribution). With $\gamma^2 \rightarrow -\infty$, $g_{ff}(T) \rightarrow 1.224$ and 1.1 for $\kappa = 2$ and $\kappa \rightarrow \infty$, respectively. As the total Gaunt factor decreases with increase in κ , the losses of energy due to free-free emission follow the same path as a result of Eq. (13).

4. Tables

Temperature-averaged and total free-free Gaunt factors calculated for $\kappa = 2, 3, 5, 10, 15, 25$, and 50 and Maxwellian distributions are displayed in Tables A.1–A.8 ($\langle g_{ff}(\gamma^2, u) \rangle$ vs. γ^2 for different u) and B.1. The parameter space in display comprises $\gamma^2 \in [10^{-8}, 10^{10}]$ and $u \in [10^{-4}, 10^4]$, but our calculations¹, cover a wider range in these parameters. More data can be provided by the authors upon request.

5. Final remarks

Optically thin plasmas in the interstellar medium may deviate from thermal equilibrium and thus, electrons are no longer described by the Maxwellian distribution. Instead they can be described by κ -distributions. These have been used to explain the deviations between derived abundances and temperatures in

¹ The publically available data in <http://www.lca.uevora.pt>

HII regions and planetary nebulae. Free-free emission dominates the cooling function of optically thin plasmas at temperatures greater than 10^7 K. The free-free spectrum and radiative losses depend on the temperature-averaged (over the electron energy) and total Gaunt factors, respectively. Thus, there is a need to calculate and make available these factors to be used by any software that deals with plasma emission.

Notable astrophysical plasmas, which are dominated by free-free emission, apart from supernova remnants and superbubbles in the interstellar medium, are the intracluster and intergalactic media in clusters of galaxies, for instance, where the hot medium dominates the baryonic matter. In particular, merger events in which smaller clusters and groups of galaxies fall into larger ones are accompanied by shocks, and hence deviations from thermal equilibrium are expected. On a larger scale still, structure formation shocks can develop as a consequence of gas infall onto dark matter halos, thereby converting gravitational into thermal energy (see, e.g., Pfrommer et al. 2006). The missing-baryon problem and its possible solution by the existence of a widespread warm hot intergalactic medium (see Cen & Ostriker 1999, 2006) is another example for the importance of free-free emission at high temperatures. In many of these contexts, κ -distributions are therefore expected to provide a better description than assuming a Maxwellian.

Here we have recalculated the nonrelativistic free-free Gaunt factor and its temperature averaged over a large spectrum of κ parameters (including the Maxwellian distribution) and integrated it over the frequency to obtain the total Gaunt factor. We found that the κ parameter most affects the temperature-averaged and total Gaunt factor at lower temperatures.
